Q.51

Test 5 Collective Grammar 1 to 4

ENGLISH Unit Wise

The Sun today is a yellow dwarf star. It is fueled by thermonuclear reactions near its center that convert hydrogen to helium. The Sun has existed in its present state for about 4 billion, 600 million years and is thousands of times larger than the Earth.

By studying other stars, astronomers can predict what the rest of the Sun's life will be like.

About 5 billion years from now, the core of the Sun will shrink and become hotter. The surface temperature will fall. The higher temperature of the center will increase the rate of thermonuclear reactions. The outer regions of the Sun will expand approximately 35 million miles, about the distance to Mercury, which is the closest planet to the Sun. The Sun will then be a red giant star. Temperatures on the Earth will become too hot for life to exist.

Once the Sun has used up its thermonuclear energy as a red giant, it will begin to shrink. After it shrinks to the size of the Earth, it will become a white dwarf star. The Sun may throw off huge amounts of gases in violent eruptions called nova explosions as it changes from a red giant to a white dwarf.

After billions of years as a white dwarf, the Sun will have used up all its fuel and will have lost its heat. Such a star is called a black dwarf. After the sun has become a black dwarf, the Earth dark and cold. If any atmosphere remains there, it will have frozen onto the Earth's surface.

What is the primary purpose of this passage?

- (A) To alert people to the dangers posed by the Sun.
- (B) To discuss conditions on Earth in the far future.
- (C) To present a theory about red giant stars.
- (D) To describe changes that the Sun will go through.

Q.54

Test 5 Collective Grammar 1 to 4

ENGLISH Unit Wise

The Sun today is a yellow dwarf star. It is fueled by thermonuclear reactions near its center that convert hydrogen to helium. The Sun has existed in its present state for about 4 billion, 600 million years and is thousands of times larger than the Earth.

By studying other stars, astronomers can predict what the rest of the Sun's life will be like.

About 5 billion years from now, the core of the Sun will shrink and become hotter. The surface temperature will fall. The higher temperature of the center will increase the rate of thermonuclear reactions. The outer regions of the Sun will expand approximately 35 million miles, about the distance to Mercury, which is the closest planet to the Sun. The Sun will then be a red giant star. Temperatures on the Earth will become too hot for life to exist.

Once the Sun has used up its thermonuclear energy as a red giant, it will begin to shrink. After it shrinks to the size of the Earth, it will become a white dwarf star. The Sun may throw off huge amounts of gases in violent eruptions called nova explosions as it changes from a red giant to a white dwarf.

After billions of years as a white dwarf, the Sun will have used up all its fuel and will have lost its heat. Such a star is called a black dwarf. After the sun has become a black dwarf, the Earth dark and cold. If any atmosphere remains there, it will have frozen onto the Earth's surface.

It can be inferred from the passage that the Sun

- (A) is approximately halfway through its life as a yellow dwarf
- (B) has been in existence for 10 billion years
- (C) is rapidly changing in size and mass
- (D) will continue as a yellow dwarf for another 10 billion years

Q.55

Test 5 Collective Grammar 1 to 4

ENGLISH Unit Wise

The Sun today is a yellow dwarf star. It is fueled by thermonuclear reactions near its center that convert hydrogen to helium. The Sun has existed in its present state for about 4 billion, 600 million years and is thousands of times larger than the Earth.

By studying other stars, astronomers can predict what the rest of the Sun's life will be like.

About 5 billion years from now, the core of the Sun will shrink and become hotter. The surface temperature will fall. The higher temperature of the center will increase the rate of thermonuclear reactions. The outer regions of the Sun will expand approximately 35 million miles, about the distance to Mercury, which is the closest planet to the Sun. The Sun will then be a red giant star. Temperatures on the Earth will become too hot for life to exist.

Once the Sun has used up its thermonuclear energy as a red giant, it will begin to shrink. After it shrinks to the size of the Earth, it will become a white dwarf star. The Sun may throw off huge amounts of gases in violent eruptions called nova explosions as it changes from a red giant to a white dwarf.

After billions of years as a white dwarf, the Sun will have used up all its fuel and will have lost its heat. Such a star is called a black dwarf. After the sun has become a black dwarf, the Earth dark and cold. If any atmosphere remains there, it will have frozen onto the Earth's surface.

What will probably be the first stage of change as the Sun becomes a red giant?

- (A) Its core will cool off and use less fuel.
- (B) Its surface will become hotter and shrink.
- (C) It will throw off huge amounts of gases.
- (D) Its center will grow smaller and hotter.

STAR INSTITUTE LAHORE

The Sun today is a yellow dwarf star. It is fueled by thermonuclear reactions near its center that convert hydrogen to helium. The Sun has existed in its present state for about 4 billion, 600 million years and is thousands of times larger than the Earth.

By studying other stars, astronomers can predict what the rest of the Sun's life will be like. About 5 billion years from now, the core of the Sun will shrink and become hotter. The surface temperature will fall. The higher temperature of the center will increase the rate of thermonuclear reactions. The outer regions of the Sun will expand approximately 35 million miles, about the distance to Mercury, which is the closest planet to the Sun. The Sun will then be a red giant star. Temperatures on the Earth will become too hot for life to exist.

Once the Sun has used up its thermonuclear energy as a red giant, it will begin to shrink. After it shrinks to the size of the Earth, it will become a white dwarf star. The Sun may throw off huge amounts of gases in violent eruptions called nova explosions as it changes from a red' giant to a white dwarf.

After billions of years as a white dwarf, the Sun will have used up all its fuel and will have lost its heat. Such a star is called a black dwarf. After the sun has become a black dwarf, the Earth dark and cold. If any atmosphere remains there, it will have frozen onto the Earth's surface.

What is the primary purpose of this passage?

- (A) To alert people to the dangers posed by the Sun.
- (B) To discuss conditions on Earth in the far future.
- (C) To present a theory about red giant stars.
- (D) To describe changes that the Sun will go through.

Q.52

Test 5 Collective Grammar 1 to 4

After billions of years as a white dwarf, the Sun will have used up all its fuel and will have lost its heat. Such a star is called a black dwarf. After the sun has become a black dwarf, the Earth dark and cold. If any atmosphere remains there, it will have frozen onto the Earth's surface.

It can be inferred from the passage that the Sun

- (A) is approximately halfway through its life as a yellow dwarf**
- (B) has been in existence for 10 billion years**
- (C) is rapidly changing in size and mass**
- (D) will continue as a yellow dwarf for another 10 billion years**

Star2021's screen

The Sun today is a yellow dwarf star. It is **fueled** by thermonuclear reactions near its center that convert hydrogen to helium. **The Sun has existed in its present state for about 4 billion, 600 million years and is thousands of times larger than the Earth.**

By studying other stars, astronomers can predict what the rest of the Sun's life will be like.

About 5 billion years from now, **the core of the Sun will shrink and become hotter.** The surface temperature will fall. The higher temperature of the center will increase the rate of thermonuclear reactions. The outer regions of the Sun will expand approximately 35 million miles, about the distance to Mercury, which is the closest planet to the Sun. The Sun will then be a red giant star. **Temperatures on the Earth will become too hot for life to exist.**

Once the Sun has used up its thermonuclear energy as a red giant, **it will begin to shrink. After it shrinks to the size of the Earth,** it will become a white dwarf star. The Sun may throw off huge amounts of gases in violent eruptions called nova explosions as it changes from a red giant to a white dwarf.

After billions of years as a white dwarf, the Sun will have used up all its fuel and will have lost its heat. Such a star is called a black dwarf. After the sun has become a black dwarf, the Earth dark and cold. If any atmosphere remains there, it will have frozen onto the Earth's surface.

What will probably be the first stage of change as the Sun becomes a red giant?

- (A) Its core will cool off and use less fuel.
- (B) Its surface will become hotter and shrink.
- (C) It will throw off huge amounts of gases.
- (D) **Its center will grow smaller and hotter.**

ENGLISH Unit Wise

The Sun today is a yellow dwarf star. It is fueled by thermonuclear reactions near its center that convert hydrogen to helium. The Sun has existed in its present state for about 4 billion, 600 million years and is thousands of times larger than the Earth.

By studying other stars, astronomers can predict what the rest of the Sun's life will be like.

About 5 billion years from now, the core of the Sun will shrink and become hotter. The surface temperature will fall. The higher temperature of the center will increase the rate of thermonuclear reactions. The outer regions of the Sun will expand approximately 35 million miles, about the distance to Mercury, which is the closest planet to the Sun. The Sun will then be a red giant star. Temperatures on the Earth will become too hot for life to exist.

Once the Sun has used up its thermonuclear energy as a red giant, it will begin to shrink. After it shrinks to the size of the Earth, it will become a white dwarf star. The Sun may throw off huge amounts of gases in violent eruptions called nova explosions as it changes from a red giant to a white dwarf.

After billions of years as a white dwarf, the Sun will have used up all its fuel and will have lost its heat. Such a star is called a black dwarf. After the sun has become a black dwarf, the Earth dark and cold. If any atmosphere remains there, it will have frozen onto the Earth's surface.

When the Sun becomes a red giant, what will conditions be like on Earth?

- (A) Its atmosphere will freeze and become solid:
- (B) It will be enveloped in the expanding surface of the Sun.
- (C) It will become too hot for life to exist
- (D) It will be nearly destroyed by nova explosions.

The Sun will then be a red giant star. **Temperatures on the Earth will become too hot for life to exist.**

Once the Sun has used up its thermonuclear energy as a red giant, **it will begin to shrink.** After it **shrinks to the size of the Earth,** it will become a white dwarf star. The Sun may throw off huge amounts of gases in violent eruptions called nova explosions as it changes from a red' giant to a white dwarf.

After billions of years as a white dwarf, the Sun will have used up all its fuel and will have lost its heat. Such a star is called a black dwarf. After the sun has become a black dwarf, the Earth dark and cold. If any atmosphere remains there, it will have frozen onto the Earth's surface.

As a white dwarf, the Sun will be

- (A) the same size as the planet Mercury
- (B) thousands of times smaller than it is today**
- (C) around 35 million miles in diameter
- (D) cold and dark
